Relational Rules

- 1) First Normal Form: a relation should always be in first normal form, a relation in first normal form only if each attribute of the domain contains one single value.
- 2) Access Rows by Content Only: We should only be able to access what the content of the database is, not where it resides within the data base
- 3) All Rows Must Be Unique: if a row is not unique it is violating both of the previous rules. If the rows are not unique then the relation is not in normal form.
